

GALLERIES V AND VI SECRETS OF TIFFANY GLASSMAKING

LOUIS COMFORT TIFFANY (1848–1933) began his work in glass with the same tools and ingredients that had been used by artisans for thousands of years before him. Tiffany took the science of glassmaking, however, and elevated it to an art form of new brilliance and beauty. Under his watch, teams of talented designers and craftspeople translated Tiffany's all-encompassing vision into some of the most memorable glass creations of our time. Tiffany's studio system was not a simple enterprise; he needed specialized employees—a hierarchy of artists and artisans—to accomplish his goals.

This exhibition addresses the processes that Tiffany's many companies used to produce everything from glass mosaics and molded buttons to leaded-glass lamps and windows.

Unless otherwise noted, all objects were designed by Louis Comfort Tiffany or one of his artists and made under the name of one of his companies.

GALLERY V

I. Leaded-glass Lampshades

The creation of a leaded-glass lampshade began with a color sketch on paper of the lamp design. Next, using pencil, watercolor, and paint, an artist copied the design onto a plaster form in the shape of the shade so that it could be assessed as a three-dimensional object. The design was finally inscribed on a wooden form. Templates for each individual piece of glass that made up the shade were created using the design on this mold, and the leaded-glass shade was assembled on it.

Standardization and bottom-line concerns governed lamp production. Often the templates were fashioned out of brass, which lasted longer than other materials and could be used multiple times in filling orders for the same lampshade design.

When beginning the shade's assembly, a brass ring was placed on top of the wood mold to create an aperture. The artisan then wrapped selected glass pieces—each cut using the brass patterns—in copper foil and positioned

Workers in the Tiffany lamp department, c. 1898.
Photograph from Cosmopolitan, 1899.

them on the mold with small nails. Starting at the top and working down, glass pieces were soldered first to the aperture ring and then one by one to each other. When this process was finished, the shade was removed from the mold and turned upside down to add a rim to the bottom edge and stabilize the shape. The shade was then soldered on the inside and beaded on the outside. Beading is a heavier application of solder to smooth and round out the line and to protect the copper-foiled edges. After soldering, the shade was patinated to change the color of the solder lines.

The ledger in this exhibition—which lists weekly fees paid to staff in the Women's Glass Cutting Department—illustrates the careful attention to financial detail.

This lamp is on view in *Louis Comfort Tiffany's Life and Art* gallery in the Laurelton Hall galleries.

Lampshade, c. 1910. *Dragonfly & Water* design, leaded glass, Clara Driscoll, designer (69-004).

THE WOMEN'S GLASS CUTTING DEPARTMENT

The design and production of lampshades was primarily accomplished within the Women's Glass Cutting Department. Tiffany established the department at his studio in 1892, allowing women for the first time to cut and select glass for windows and mosaics along with the men. Tiffany employed six women at his glasshouse in Corona, New York, in 1892. By 1897, Tiffany had between forty and fifty women employed in his glass workshop, who were known as "the Tiffany Girls." Clara Driscoll (1861–1944), supervisor of the department, designed many lampshades, including the popular *Dragonfly & Water* shade that was awarded a medal at the 1900 Paris world's fair. Women were respected for their color sense and ability to cut glass for the most intricate patterns.

II. Blown Glass

Glassblowing is a team activity that employs the talents of many artisans. Typically, a supervisor known as a gaffer manages a group of five to seven people who comprise one shop.

To create a blown-glass object, glass ingredients must first be heated to a molten state of 2,400 degrees Fahrenheit. These are the next steps:

Shaping: An artisan collects a gob of the hot, liquified glass, known as a gather, from the working furnace on the end of a metal blowpipe, a hollow rod, usually five feet long. The molten glass is blown, rolled, pulled, and manipulated with various tools into the shape desired. During this phase, the object is taken frequently to a reheating furnace commonly referred to as a gally hole.

Finishing: The shaped object is transferred from the blowpipe to a pontil, a long, solid metal rod, for additional sculpting and added details.

Cooling: The completed glass object must be placed in an annealing oven to cool gradually over time. If glass objects are not annealed, they will crack or break.

1) Left to right:

Vase, c. 1903

Carnation

Blown glass

Marks: 9542A / L.C.T.

(U-035)

On its base, this vessel shows the mark (the round, shiny area in the center) left by the pontil. The number within the pontil mark is the Morse Museum's identifying accession number. The initials L.C.T. are etched on the left-hand side of the pontil mark. The number 9542A, a unique production number that is helpful in dating this object, is at the bottom of the pontil mark.

Vase, c. 1903

Carnation

Blown glass

Marks: 9475A / L.C.T.

(U-036)

Glass with an iridescent appearance is created by adding metallic materials to the primary ingredients of glass—silica, soda or potash, and lime. Iridescence can also be achieved by spraying a glass object's surface with stannous or lead chloride before heating it in an oxygen-deprived atmosphere.

Favrite –
Exhibition Piece
(78-0228)

Tiffany's Cypriote glass has the rough, irregular, and pitted surface that was common in glass buried for centuries. Tiffany artisans likely reproduced this effect by rolling molten glass in crushed glass pieces.

2) Glassblowing Tools

These tools are modern examples similar to those that would have been used at Tiffany's companies.

Blowpipe: Used to create the approximate mass and the general design of the object being developed.

Casting Ladle: Used to transfer hot glass into a cast.

Duck Bill Shears: Used to cut glass and often to trim and shape a piece.

Jordan Jacks: Used to shape glass as well as to open a glass vessel.

Paddle: Used to shape glass.

Pontil: Used after the blowpipe for further shaping and finishing touches.

Tongs: Used to take items from the pontil to the annealing oven.

GALLERY VI

III. Opalescent Glass

The glass made at Tiffany Studios was called opalescent glass. It was radically different from pot metal, a type of glass commonly used in Tiffany's era. Pot metal was uniformly colored, translucent, and regular in every way. Craftspeople making pot metal windows often painted them with enamels—a glass paste—to create form and visual effects.

By contrast, opalescent glass was fabulously varied in color and texture—even within a single piece of glass. By careful selection, Tiffany could use his glass to mimic foliage, fabric, water, or a sunlit horizon. Tiffany, in a sense, was painting with glass, as opposed to painting on glass. He applied for and received patents for his modifications and improvements upon opalescent glass, although John La Farge (1835–1910) first patented the underlying process in 1879.

Tiffany used the word *Favrile* as a general trademark. The term, meaning made by hand, was used to describe Tiffany's glass, pottery, and metalware.

Touch Box

Tiffany glass was created in a variety of ways. Some glass types were rolled out onto a flat surface and manipulated.

To create the cloth-like **drapery glass (DG)** artisans used hand tools to move and twist hot glass into folds.

Mixing two or more colors of molten glass together created **streaky or striated glass (SG)**.

Foliage (FG) or confetti glass (CG) was made by pouring molten glass on top of pieces of colored glass or by sprinkling pieces of colored glass into hot glass.

Some of these terms for glass types are merely descriptive and were not necessarily used by Tiffany.

IV. Leaded-Glass Windows

The creation of a Tiffany leaded-glass window began with a small sketch or drawing that was followed by a cartoon, a full-scale painting of the proposed window. (See the cartoon for Yale University's *Education* window in the Museum's lobby). Then the designer made two cutlines—tracings of the cartoon on which the planned

glass cuts were carefully marked in thick black line. The first cutline served as the pattern for the window. The second was cut into templates to be used to produce the many individual glass shapes and sizes required by the pattern. Next, glass for the window design was chosen from stored sheets available in thousands of colors and textures. Once all of the glass for the window was selected and cut, the window was put together in one of two ways:

Leaded-glass technique: Artisans fit the cut glass into flexible lead cames, which are strips of lead shaped like construction “I-beams.” The glass pieces are placed on either side of the “I” and soldered and mitered at the joints.

Copper-foil technique: Lead cames were difficult to use for complex patterns requiring many small glass pieces. For these projects, especially the leaded-glass lampshades, artisans wrapped the edges of glass pieces with a thin copper foil before they were laid out and soldered together. This copper foil was treated with beeswax on one side and muriatic acid on the other. The beeswax permitted the foil to adhere to the glass, while the muriatic acid permitted solder to bond to the foil.

- 2) **Lead lines from Faith window, c. 1896**
First Presbyterian Church,
Lake Forest, Illinois
These lead lines were removed during the window’s conservation. Lead deteriorates over time and needs to be replaced. The lead lines are taken off as a whole so that the conservator has a guide to follow.

METALLIC OXIDES PRODUCE COLOR

Iron	→	Green
Cobalt	→	Blue
Manganese	→	Amethyst/Purple
Tin	→	White
Iron/Sulfur	→	Ambers/Browns
Lead Antimony	→	Yellow
Gold/Other Metals	→	Red

V. Glass Chemistry

Silica (most commonly sand), soda or potash, and lime are the three primary ingredients of glass. When mixed, these raw materials form what artisans refer to as batch. Color is created in various ways, but often by adding either metallic oxides to the batch or various ready-made forms of colored glass during other stages of the glassmaking process.

- B) Sand
- C) Glass rods, small and large
- D) Metallic oxides
- E) Billets (large chunks of glass)

**VI. Molded and
Pressed Glass**

Tiffany produced a variety of glass tiles, jewels, and buttons in molds or with presses. In the molding process, molten glass was poured, blown, or pressed into a mold typically made of metal. The green buttons in this display were made with a special press to imprint the design, but no mold was used. An object produced solely with a press has an irregular border.

(2004-024)

VII. Glass Mosaic

Tiffany began experimenting with mosaics in the early 1870s. The glass pieces used for mosaics, often about one-quarter-inch square, are called tesserae and are cut from sheets of colored glass.
